

C2: ordinary CLI, recovery deferred

Final proposed r2 · C2b-ordinary-v1 · AC04/05/09 partial
[Exact contract and adoption retry table](#) · [F1–F4 dispositions](#)

Parent adopted the findings and scope direction. Final independent review and dispatch remain pending; human approval is unconfirmed. Design only.

1. Stop the unsupported path

F1: the inspected Docker candidate is unavailable; there is no qualified pre-admission identity or complete-lifetime evidence producer. Defer recovery records, gate predicates, qualifiers and positive recovery. **F2:** defer live v1→v2 migration; the bounded local check found no canonical continuing guard ledgers. Original schemas and historical evidence remain intact.

C2b-ordinary-v1: implement `status`, `next`, `record`, `close`, `adopt` after review. Help and the operator guide must list these five supported verbs. The original sixth verb, `recover`, remains explicitly blocked/future: no subcommand stub. Overall C2 and AC05 are incomplete.

2. Small explicit core exception

Component / AC	Exact boundary
State · 04/05/09	Extract existing <code>_load_design</code> checks into <code>validate_design_binding(root, contract, design, ledger)</code> . Ordinary loading still reads the live pointer; adopt validates prospective documents. Add paired optional <code>design / ledger</code> keywords to <code>bind_inputs</code> for validated old-basis evaluation during partial publication. No relaxed check.
CLI · 04/05/09	One lexical lock; revalidate → admission/intent → actual observer → normal completion/receipt. Finite adopt-only publication below.
Gate / runner · 05/09	Frozen: v1 records, eight observer fields, pure readiness, requires graph, exact receipt chronology and prefix caches.

Why: shared validation/materialization avoids duplicated policy and load-before-adoption dead ends. Parent must authorize these exact C1 seams before edits.

3. Ordinary adopt: validate before publication

Stage immutable revision HTML, normative contract, and existing-schema workflow/current-design documents. `--review` supplies matching existing DesignReview metadata and the unchanged independent report. Validate old and prospective triples through the shared helper.

Initial: absent authority → exclusive empty v1 ledger → adopted event → workflow → pointer → normal load.

Revision: retain exact old design inputs, validate → append one adopted event → workflow → pointer. These are design documents, not a migration archive or second runtime journal.

The linked finite table permits only exact empty-basis, old-pair, event-before-publication, workflow-before-pointer and already-published retries. Conflicting/partial bytes stop. Only adopt raw-reads these named inputs; other verbs still fail normal load on an incomplete publication. An orphan lexical lock blocks even retry—never steal it.

4. Boundaries and acceptance

F3: unknown spawn blocks every currently unsupported recovery. A future complete-environment-reset exception needs qualified pre-admission bindings. No fabricated events, lock deletion/age/PID/root-exit shortcut, automatic replay or new-worktree-as-reset. Full durable recovery ownership is deferred, not hidden in reason.

F4: exact reviewed bytes resolve before append; ledger sequence proves acceptance ordering. No invented review wall clock. Future platform temporal qualification remains separate. Legacy completion/handoff, actual Git close checks, required independent proof and Q2–Q5 missing metrics retain their policies.

After review: focused shared-validator proof, then ordinary CLI/adoption failure-table and real no-spawn/resume tests, then independent verification/review. No recovery or new quality pass. Parent renders this two-page-target overview. Any remaining material finding stops that path; this is the last planned design round.
