

C2 recovery: authority, not a label

Proposed r1 · AC04 / AC05 / AC09 · HEAD d971634
[Exact fields, interfaces, migration and test matrix](#) · [Grounding and validation notes](#)

Design only. Parent owns independent review and final adoption. Human approval remains unconfirmed under unattended authorization. No implementation, new recovery experiment or quality claim.

1. Observed blocker → bounded correction

FACT: state validates only the old event fields and requires terminal observations for completion. Gate lifetime resolution recognizes only completion. The lexical mutex unlinks in `finally`. Thus unknown-spawn recovery cannot be represented without inventing process facts. The existing [pinned diagnosis](#) remains sufficient; its seven source/contract hashes were reconciled, not its production scenario rerun.

2. Minimal component delta

Owner / why	What changes / how
State · 04/05/09	Ledger/Event v2; admitted <code>lock_owner</code> , recovered <code>recovery_ref</code> . Ordinary resolved dataclasses mirror receipt resolution. Immutable bytes and exact admission/basis hashes prevent substitution.
Gate · 04/05/09	<code>recovery_resolves(run_id)</code> consumes qualified materialized facts; preserve public evaluate signature, requires graph, exact receipt chronology and evaluation-local prefix caches. No I/O.
CLI · 04/05/09	Persist owner before launch; validate captures/review, append interrupted then recovered, remove only matching stale lock after guard-inactivity proof. Short acquisition claim serializes replacement; orphan claim stays blocked.

Six verbs/options, eight-field observer and standalone locks stay unchanged. Recovery never creates successful work, red, check proof, closure or automatic replay.

3. Compatibility and failure contract

Archive original v1 ledger bytes; v2 retains its exact event prefix and marks every new event v2. Locked adopt alone upgrades, with no unresolved legacy executable run. Legacy unknown runs cannot acquire invented ownership. Historical successful receipts keep their policy. Pointer/archive mismatch fails closed; nothing is retrospectively admitted.

Missing/tampered captures, wrong run/token/guard, stale basis/adoption, unsupported coverage and independent-review mismatch cannot unlock. Malformed submission is exit 2; uncertain recovery/conflict is 3. Exact partial-write retries preserve sequence and evidence; different evidence or intervening events require reconciliation, not rewriting.

4. Platform qualification is separately blocked

No actual positive recovery path is established here. The runner emits null creation identity; Windows group creation/taskkill and the test's retained direct-process handle do not establish durable guard identity or complete descendant death. No reset API, supervisor or authenticated operator is assumed.

Accept the finite data/control seam separately. Before live recovery can pass, qualify one actual evidence producer and decoder proving matched guard inactivity plus complete admitted tree termination or environment reset. Raw hashes and independent attribution are necessary, not sufficient. Otherwise preserve the blocked workspace and continue only in an externally verified clean execution environment with new adoption and fresh checks; a new directory is not isolation.

5. Small execution grouping after review

C2R-D: one state/gate context: strict records → immutable resolver → pure predicate → targeted legacy/chronology/tamper/cache tests → independent verification and review. Then the existing C2b owner wires CLI and real negative crash/lock tests. Synthetic resolved-proof positives are labeled protocol tests only.

C2R-P: separate supported-platform qualification and real CLI positive, or retain the explicit blocker. Reopen affected C1 persistence, resolved-view and gate proof; keep old results historical. C2a runner stays frozen. Q2–Q5 actual metrics and later host exercises remain required and separate. Parent next: review this amendment and accept or revise the split—not declare end-to-end recovery implemented.
